

Python Programming Fundamentals

BankAccount Class

Programming Fundamentals Team

SETU

2026-06-12

Outline

1. Designing the BankAccount Class
2. BankAccount — First Version
3. Creating and Using Instances
4. Problems with the First Version
5. BankAccount with Validation
6. The __str__ Method
7. Transaction History

Outline

1. Designing the BankAccount Class

2. BankAccount — First Version

3. Creating and Using Instances

4. Problems with the First Version

5. BankAccount with Validation

6. The `__str__` Method

7. Transaction History

1. Designing the BankAccount Class

Let's build a BankAccount class step by step.

What state does a bank account have?

- Account number
- Account holder name
- Current balance

1. Designing the BankAccount Class

Let's build a BankAccount class step by step.

What state does a bank account have?

- Account number
- Account holder name
- Current balance

What can a bank account do?

- Deposit money
- Withdraw money
- Get current balance
- Display account information

1. Designing the BankAccount Class

Let's build a BankAccount class step by step.

What state does a bank account have?

- Account number
- Account holder name
- Current balance

What can a bank account do?

- Deposit money
- Withdraw money
- Get current balance
- Display account information

This is the process of **object-oriented design**: identify the **attributes** (state) and **methods** (behaviour) before writing any code.

Outline

1. Designing the BankAccount Class
- 2. BankAccount — First Version**
3. Creating and Using Instances
4. Problems with the First Version
5. BankAccount with Validation
6. The __str__ Method
7. Transaction History

2. BankAccount – First Version

```
class BankAccount:
    """A simple bank account."""

    def __init__(self, account_no, name, initial_balance=0):
        self.account_no = account_no
        self.name        = name
        self.balance      = initial_balance

    def deposit(self, amount):
        """Add amount to balance."""
        self.balance += amount

    def withdraw(self, amount):
        """Subtract amount from balance."""
        self.balance -= amount
```

2. BankAccount — First Version

```
def get_balance(self):  
    """Return current balance."""  
    return self.balance  
  
def __str__(self):  
    return f"Account {self.account_no} ({self.name}):  
€{self.balance:.2f}"
```

Outline

1. Designing the BankAccount Class
2. BankAccount — First Version
- 3. Creating and Using Instances**
4. Problems with the First Version
5. BankAccount with Validation
6. The __str__ Method
7. Transaction History

3. Creating and Using Instances

```
# Create two separate accounts
alice_account = BankAccount("ACC001", "Alice Murphy", 500)
bob_account    = BankAccount("ACC002", "Bob Kelly")

# Each object has its own independent state
print(alice_account)      # Account ACC001 (Alice Murphy): €500.00
print(bob_account)        # Account ACC002 (Bob Kelly): €0.00

# Make some transactions
alice_account.deposit(200)
alice_account.withdraw(75)
bob_account.deposit(1000)
bob_account.deposit(500)
bob_account.withdraw(200)

print(alice_account)      # Account ACC001 (Alice Murphy): €625.00
```

3. Creating and Using Instances

```
print(bob_account)          # Account ACC002 (Bob Kelly): €1300.00

# Access balance directly
print(f"Alice's balance: €{alice_account.get_balance():.2f}")
```

Outline

1. Designing the BankAccount Class
2. BankAccount — First Version
3. Creating and Using Instances
- 4. Problems with the First Version**
5. BankAccount with Validation
6. The __str__ Method
7. Transaction History

4. Problems with the First Version

The current version has no validation:

```
acc = BankAccount("ACC003", "Carol", 100)
```

```
# These should all be rejected!
```

```
acc.withdraw(500)           # overdraft – balance becomes negative
```

```
acc.deposit(-50)           # negative deposit?!
```

```
acc.withdraw(-10)          # negative withdrawal adds money!
```

```
print(acc)    # Account ACC003 (Carol): €-440.00
```

4. Problems with the First Version

The current version has no validation:

```
acc = BankAccount("ACC003", "Carol", 100)
```

```
# These should all be rejected!
```

```
acc.withdraw(500)           # overdraft – balance becomes negative
```

```
acc.deposit(-50)           # negative deposit?!
```

```
acc.withdraw(-10)          # negative withdrawal adds money!
```

```
print(acc)   # Account ACC003 (Carol): €-440.00
```

We need to add validation:

- Deposit amount must be positive
- Withdrawal amount must be positive
- Cannot withdraw more than the current balance

Outline

1. Designing the BankAccount Class
2. BankAccount — First Version
3. Creating and Using Instances
4. Problems with the First Version
- 5. BankAccount with Validation**
6. The __str__ Method
7. Transaction History

5. BankAccount with Validation

```
class BankAccount:
    def __init__(self, account_no, name, initial_balance=0):
        if initial_balance < 0:
            raise ValueError("Initial balance cannot be negative")
        self.account_no = account_no
        self.name = name
        self.balance = initial_balance

    def deposit(self, amount):
        if amount <= 0:
            raise ValueError(f"Deposit amount must be positive, got {amount}")
        self.balance += amount
        print(f"Deposited €{amount:.2f}. New balance: €{self.balance:.2f}")

    def withdraw(self, amount):
```

5. BankAccount with Validation

```
if amount <= 0:
    raise ValueError(f"Withdrawal amount must be positive, got {amount}")
if amount > self.balance:
    raise ValueError(f"Insufficient funds. Balance: €{self.balance:.2f}")
self.balance -= amount
print(f"Withdrew €{amount:.2f}. New balance: €{self.balance:.2f}")
```

Outline

1. Designing the BankAccount Class
2. BankAccount — First Version
3. Creating and Using Instances
4. Problems with the First Version
5. BankAccount with Validation
- 6. The `__str__` Method**
7. Transaction History

6. The __str__ Method

```
def __str__(self):  
    return (f"BankAccount(\n"  
            f"    Account No: {self.account_no}\n"  
            f"    Holder:      {self.name}\n"  
            f"    Balance:     €{self.balance:.2f}\n"  
            f")")
```

6. The `__str__` Method

6. The __str__ Method

```
def __str__(self):  
    return (f"BankAccount(\n"  
            f"  Account No: {self.account_no}\n"  
            f"  Holder:      {self.name}\n"  
            f"  Balance:     €{self.balance:.2f}\n"  
            f")")
```

Using the validated BankAccount:

```
acc = BankAccount("ACC001", "Alice", 1000)  
  
acc.deposit(500)           # OK  
acc.withdraw(200)          # OK  
  
try:  
    acc.withdraw(2000)      # raises ValueError
```

6. The __str__ Method

```
except ValueError as e:
    print(f"Error: {e}")

try:
    acc.deposit(-50)      # raises ValueError
except ValueError as e:
    print(f"Error: {e}")

print(acc)
```

Outline

1. Designing the BankAccount Class
2. BankAccount — First Version
3. Creating and Using Instances
4. Problems with the First Version
5. BankAccount with Validation
6. The __str__ Method
- 7. Transaction History**

7. Transaction History

Extending BankAccount with a transaction log:

```
class BankAccount:
    def __init__(self, account_no, name, initial_balance=0):
        self.account_no = account_no
        self.name = name
        self.balance = initial_balance
        self.transactions = []      # list to hold history

    def deposit(self, amount):
        if amount <= 0:
            raise ValueError("Deposit must be positive")
        self.balance += amount
        self.transactions.append(("Deposit", amount, self.balance))

    def withdraw(self, amount):
```

7. Transaction History

```
if amount <= 0:
    raise ValueError("Withdrawal must be positive")
if amount > self.balance:
    raise ValueError("Insufficient funds")
self.balance -= amount
self.transactions.append(("Withdrawal", amount, self.balance))

def print_statement(self):
    print(f"Statement for {self.name} ({self.account_no})")
    print("-" * 45)
    for t_type, amount, balance in self.transactions:
        print(f"  {t_type:<12} €{amount:>8.2f}    Balance:
€{balance:.2f}")
```

Thanks for Watching - Any questions?
